

**1(a) Proof.** We fix  $c \in (a, b)$ . We need to show that  $\text{LHS} \leq \text{RHS}$  and  $\text{LHS} \geq \text{RHS}$ . Let partition  $P$  on  $[a, b]$  be arbitrary. Then let  $P^*$  be its refinement by adding the point  $c$ . Then split  $P^*$  into  $P_1$  and  $P_2$ , where  $P_1$  is a partition for  $[a, c]$  and  $P_2$  is a partition for  $[c, b]$ . Then,

$$\begin{aligned} U(P, f|_{[a,b]}) &\geq U(P^*, f|_{[a,b]}) = U(P_1, f|_{[a,c]}) + U(P_2, f|_{[c,b]}) \geq \inf_P U(P, f|_{[a,c]}) + \inf_P U(P, f|_{[c,b]}) \\ &= \int_a^c f \, d\alpha + \int_c^b f \, d\alpha. \end{aligned}$$

This means that  $\int_a^c f \, d\alpha + \int_c^b f \, d\alpha$  is a lower bound for  $U(P, f|_{[a,b]})$  over all partitions of  $[a, b]$ , so it must be smaller than the greatest lower bound. Therefore,

$$\int_a^b f \, d\alpha = \inf_P U(P, f|_{[a,b]}) \geq \int_a^c f \, d\alpha + \int_c^b f \, d\alpha.$$

Hence,  $\text{LHS} \geq \text{RHS}$ .

Let  $\varepsilon > 0$  be given. By the property of infimum, there must be partition  $P_1$  of  $[a, c]$  and partition  $P_2$  of  $[c, b]$  such that

$$U(P_1, f|_{[a,c]}) < \int_a^c f \, d\alpha + \frac{\varepsilon}{2}, \text{ and } U(P_2, f|_{[c,b]}) < \int_c^b f \, d\alpha + \frac{\varepsilon}{2}.$$

Note that  $P_1 \cup P_2$  is a partition for  $[a, b]$ . Therefore,

$$\int_a^b f \, d\alpha \leq U(P_1 \cup P_2, f|_{[a,b]}) = U(P_1, f|_{[a,c]}) + U(P_2, f|_{[c,b]}) < \int_a^c f \, d\alpha + \int_c^b f \, d\alpha + \varepsilon.$$

Since  $\varepsilon$  is arbitrary,

$$\int_a^b f \, d\alpha \leq \int_a^c f \, d\alpha + \int_c^b f \, d\alpha.$$

Hence,  $\text{LHS} \leq \text{RHS}$ . ■

**1(b) Proof.** First note that over any sub-interval  $[x_{i-1}, x_i] \subseteq [a, b]$ ,

$$\sup(f + g) \leq \sup f + \sup g. \quad (*)$$

To see this, let  $\varepsilon > 0$  be given. Then there exists  $x \in [x_{i-1}, x_i]$  s.t.  $\sup(f + g) - \varepsilon < (f + g)(x)$ . Therefore,

$$\sup(f + g) - \varepsilon < f(x) + g(x) \leq \sup f + \sup g.$$

And since  $\varepsilon$  is arbitrary,  $\sup(f + g) \leq \sup f + \sup g$ .

Now we are ready to prove the inequality in question. Again let  $\varepsilon > 0$  be given. Then there exist partitions  $P_1, P_2$  of  $[a, b]$  s.t.

$$U(P_1, f) < \int_a^b f \, d\alpha + \frac{\varepsilon}{2}, \text{ and } U(P_2, g) < \int_a^b g \, d\alpha + \frac{\varepsilon}{2}.$$

Let  $P^* = P_1 \cup P_2$ . By (\*),  $U(P^*, f + g) \leq U(P^*, f) + U(P^*, g)$ . Also, by property of refinement,  $U(P^*, f) \leq U(P_1, f)$  and  $U(P^*, g) \leq U(P_2, g)$ . Hence,

$$\overline{\int_a^b} f \, d\alpha \leq U(P^*, f + g) \leq U(P^*, f) + U(P^*, g) < \overline{\int_a^b} f \, d\alpha + \overline{\int_a^b} g \, d\alpha + \varepsilon.$$

And since  $\varepsilon$  is arbitrary, LHS  $\leq$  RHS as desired. ■

**1(c)** *Proof.* Let  $[a, b] = [0, 1]$  Consider  $\alpha(x) = x$  on  $[0, 1]$ . And let

$$f(x) = \begin{cases} -1 & \text{if } x \in \mathbb{Q} \cap [0, 1], \\ 1 & \text{otherwise,} \end{cases} \quad \text{and } g(x) = \begin{cases} 1 & \text{if } x \in \mathbb{Q} \cap [0, 1], \\ -1 & \text{otherwise.} \end{cases}$$

Then  $f + g = 0$  on  $[a, b]$ . Since for any sub-intervals  $[x_{i-1}, x_i]$  of  $[0, 1]$  contain both rational and irrational points,  $M_i = 1$  for both  $f$  and  $g$  for all  $i$ . Therefore,

$$0 = \overline{\int_0^1} (f + g) \, dx < \overline{\int_0^1} f \, dx + \overline{\int_0^1} g \, dx = 1 + 1 = 2. \quad \text{■}$$

**2 Proof.** For the sake of contradiction, suppose that there is indeed a bounded  $\rho \in \mathcal{R}[-1, 1]$  s.t.  $\int_{-1}^1 f(x)\rho(x) dx = f(0)$  for any  $f \in C[-1, 1]$ . Consider the following sequence of continuous functions on  $[-1, 1]$ ,

$$f_n = \begin{cases} n^2x + n & \text{if } x \in [-\frac{1}{n}, 0], \\ -n^2x + n & \text{if } x \in [0, \frac{1}{n}], \\ 0 & \text{otherwise.} \end{cases}$$

Note that each  $f_n$  forms a thin triangle of area of exactly 1 on  $[-1, 1]$  where  $f_n(0) = n$ .

Now let  $M \in \mathbb{R}$  be such that  $\sup_{x \in [-1, 1]} |\rho(x)| \leq M$ . Such  $M$  exists as  $\rho$  is bounded on  $[-1, 1]$ . Then, for all  $n \in \mathbb{N}$ ,

$$n = f_n(0) = \int_{-1}^1 f_n(x)\rho(x) dx \leq \int_{-1}^1 f_n(x)M dx = M \int_{-1}^1 f_n(x) dx = M.$$

This is a contradiction since  $\mathbb{N}$  is not bounded above. ■

**3** *Proof.*

**4(a) Proof.** Let  $\varepsilon > 0$  be arbitrary. We show that there exists a natural  $N$ , such that for all  $n > N$ ,  $|U(P_n, f) - L(P_n, f) - 0| < \varepsilon$ , or simply  $U(P_n, f) - L(P_n, f) < \varepsilon$  since  $U(P_n, f) \geq L(P_n, f)$  always true.

Since  $f \in \mathcal{R}[a, b]$ , then there exists a partition  $Q = \{q_0, q_1, \dots, q_k\}$  of  $[a, b]$  where  $U(Q, f) - L(Q, f) < \varepsilon/2$ . Let  $l_{\min}$  be the minimum length of the closed intervals  $[q_{j-1}, q_j]$  where  $j = 1, \dots, k$ .

We also know that  $f$  has to be bounded. Therefore, let  $M \geq |f(x)|$  for all  $x \in [a, b]$ .

Let  $P_n = \{x_0, x_1, \dots, x_n\}$ . We choose  $N$  so large that  $d_N = \frac{b-a}{N} < l_{\min}$ . Then by generalized pigeonhole principle, each interval  $[x_{i-1}, x_i]$  from  $P_n$  contains at most one point from  $Q$ . And note that for all  $n > N$ , such property still holds. And make  $N$  so large that  $d_N < \frac{\varepsilon/2}{2M(k-1)}$ .

Consider the partition  $Q \cup P_n$ , which is a refinement of both  $Q$  and  $P_n$ . Therefore, we know

$$U(Q \cup P_n, f) - L(Q \cup P_n, f) \leq U(P_n, f) - L(P_n, f),$$

and

$$U(Q \cup P_n, f) - L(Q \cup P_n, f) \leq U(Q, f) - L(Q, f) < \varepsilon/2.$$

Now look more closely, we first see that there are  $k-1$  points from  $Q$  that are not the end points. And therefore, there are exactly  $k-1$  intervals in the form of  $[x_{i-1}, x_i]$  from  $P_n$  ( $n > N$ ) that contains exactly one point of  $Q$ , where  $i \in \{2, 3, \dots, n-1\}$ .

Let  $D_n = [U(P_n, f) - L(P_n, f)] - [U(Q \cup P_n, f) - L(Q \cup P_n, f)]$ . And suppose  $[x_{i-1}, x_i]$  contains exactly one  $q_j$  where  $j = 2, \dots, k-2$ , define

$$\Lambda_j = \left( \sup_{x \in [x_{i-1}, q_j]} f(x) - \inf_{x \in [x_{i-1}, q_j]} f(x) \right) |x_{i-1} - q_j| + \left( \sup_{x \in [q_j, x_i]} f(x) - \inf_{x \in [q_j, x_i]} f(x) \right) |q_j - x_i|.$$

Notice that  $\Lambda_j \geq 0$  always.

Therefore, we have

$$\begin{aligned} D_N &= [U(P_N, f) - L(P_N, f)] - [U(Q \cup P_N, f) - L(Q \cup P_N, f)] \\ &= \sum_{[x_{i-1}, x_i] \cap \{q_1, \dots, q_j, \dots, q_{k-1}\} \neq \emptyset} (M_i - m_i) \Delta x_i - \Lambda_j \\ &\leq \sum_{[x_{i-1}, x_i] \cap \{q_1, \dots, q_j, \dots, q_{k-1}\} \neq \emptyset} (M_i - m_i) \Delta x_i \\ &= d_N \cdot \left( \sum_{[x_{i-1}, x_i] \cap \{q_1, \dots, q_j, \dots, q_{k-1}\} \neq \emptyset} (M_i - m_i) \right) \\ &\leq d_N \cdot \left( \sum_{[x_{i-1}, x_i] \cap \{q_1, \dots, q_j, \dots, q_{k-1}\} \neq \emptyset} 2M \right) \\ &= d_N \cdot 2M(k-1) \\ &< \varepsilon/2. \end{aligned}$$

And note that as for all  $n > N$ , we will still have  $D_n \leq d_n \cdot 2M(k-1) < \varepsilon/2$ .

Therefore, we see that for all  $n > N$ ,

$$U(P_n, f) - L(P_n, f) = U(Q \cup P_n, f) - L(Q \cup P_n, f) + D_n < \varepsilon/2 + \varepsilon/2 = \varepsilon.$$

■

**4(b)** *Proof.* We give a counter-example. Let  $[a, b] = [0, 1]$ . Let  $\phi$  be the Golden Ratio ( $\approx 0.618$ ), a irrational number. Define

$$f(x) = \begin{cases} 0, & \text{if } x < \phi \\ 1, & \text{if } x \geq \phi, \end{cases}$$

and

$$\alpha(x) = \begin{cases} 0, & \text{if } x \leq \phi \\ 1, & \text{if } x > \phi. \end{cases}$$

We can see that  $f \in \mathcal{R}(\alpha)$  on  $[0, 1]$ . Note that if we choose partition  $P = [0, \phi, 1]$ , then

$$\begin{aligned} U(P, f) - L(P, f) &= (M_1 - m_1)(\alpha(\phi) - \alpha(0)) + (M_2 - m_2)(\alpha(1) - \alpha(\phi)) \\ &= (M_2 - m_2)(\alpha(1) - \alpha(\phi)) && \text{(as } \alpha(1) = \alpha(\phi)) \\ &= 0. && \text{(as } M_2 = m_2) \end{aligned}$$

This means that for all  $\varepsilon > 0$ , there exists a partition  $P$  such that  $U(P, f) - L(P, f) < \varepsilon$ . Thus, by Rudin Theorem 6.6, we have  $f \in \mathcal{R}(\alpha)$  on  $[0, 1]$ .

Now note that for all  $n \in \mathbb{N}$ , all points in  $P_n$  remain to be rational. Therefore, no matter how large  $n$  is,  $\phi \neq p$  for all  $p \in P_n$ . And there is exactly one interval  $[x_{i-1}, x_i]$  from  $P_n$  that contains  $\phi$ .

Therefore, for any  $n \in \mathbb{N}$ ,

$$\begin{aligned} U(P_n, f, \alpha) - L(P_n, f, \alpha) &= \sum_{i=1}^n (M_i - m_i) \Delta \alpha_i \\ &= \sum_{\phi \in [x_{i-1}, x_i]} (M_i - m_i) \Delta \alpha_i \\ &= (1 - 0) \cdot (1 - 0) \\ &= 1 \end{aligned}$$

Therefore, the limit cannot go to zero. ■
